

Working Paper Report of Moral Judgement under Two-sided Tobit Models

Leonardo H. Talero-Sarmiento

2026-04-23 21:26:17

This run uses `Version 2.0/consolidado_ALL_2026_04_09_LONG.xlsx` as the only analytical source and preserves each imported row as one real judgement observation. The production estimator is a two-sided Tobit fitted with `survival::survreg`, using bilateral censoring at -9 and 9, participant-cluster robust standard errors through `cluster = id`, and `factor(session)` in every active formula.

1 Understanding the modeling strategy

The purpose of the pipeline is to explain how participants assign moral judgement to a focal negotiator within a structured experimental setting. The objective is not limited to describing average responses. Rather, the pipeline is designed to estimate how judgement changes as a function of empathy, group alignment, negotiation decisions, and role-specific relational structure. The outcome of interest is **judgement**, interpreted as the participant's moral evaluation of the target negotiator. Because each participant contributes repeated evaluations across scenarios and targets, the modeling strategy must satisfy three conditions simultaneously: it must preserve one row per real observation, respect the bounded structure of the outcome, and account for within-participant dependence. For these reasons, the production workflow uses a two-sided Tobit model with participant-cluster robust inference and session adjustment.

The need for a Tobit specification follows directly from the nature of the dependent variable. **judgement** is continuous in interpretation but bounded in measurement. Values at the extremes are therefore not ordinary unrestricted observations; they are limits imposed by the response scale. A standard linear model assumes an outcome that can vary freely over the real line, which is inappropriate when responses accumulate at lower and upper boundaries. The Tobit framework addresses this by assuming an underlying latent moral evaluation, denoted here by y_i^* , that is only observed through a bounded realized score:

$$y_i^* = X_i\beta + \varepsilon_i$$

and

$$judgement_i = \max(-9, \min(9, y_i^*)).$$

Under this specification, the model jointly represents three kinds of outcomes: interior continuous values, lower-bound pile-up, and upper-bound pile-up. In this context, censoring does not mean that data are missing. It means that the observed score is recorded at the measurement boundary whenever the latent evaluation would extend beyond the scale. The Tobit model is therefore not a technical convenience but a direct response to the design of the judgement variable itself.

A second methodological challenge arises from the repeated-measures structure of the experiment. Each participant contributes multiple rows, so the observations are not independent. Ignoring this dependence would tend to underestimate standard errors and overstate statistical significance. The current pipeline addresses this issue through participant-cluster robust standard errors using `id` as the clustering variable. Session is also incorporated because different experimental sessions may vary in context, timing, or implementation details. This is handled through `factor(session)`, which absorbs systematic session-level shifts. In the active production branch, session is therefore modeled as a fixed-effect adjustment rather than as a random session intercept. The implemented estimator is best described as a two-sided Tobit with participant-cluster robust inference and session fixed effects.

The predictors are organized into theoretically meaningful blocks. The first block contains empathy dimensions, represented by `iri_fs`, `iri_ec`, `iri_pt`, and `iri_pd`, and provides the basis for H1. The second block captures role-specific ingroup/outgroup structure and underlies H2. The acceptance block (`accept_target`, `accept_other`, and their interaction) enters as a common adjustment in H1-H5 and is the primary focus of H4. Finally, all models include sociodemographic controls such as age, SES, sex, and player faculty. This structure allows the pipeline to evaluate distinct explanatory mechanisms while preserving a coherent hypothesis architecture.

Interactions are especially important in this design because additive effects alone are unlikely to capture the logic of the experiment. In H3, empathy-by-group interactions test whether the effect of empathy depends on social alignment. In H4 and H5, the interaction between `accept_target` and `accept_other` evaluates whether the moral meaning of one negotiator’s decision depends on the counterpart’s decision. These interaction terms are theoretically motivated and reflect the fact that moral evaluation is shaped not only by isolated attributes but also by combinations of dispositions, relationships, and actions.

The distinction between victim and bystander roles is central to the entire modeling strategy. Victim models focus on victim-negotiator alignment and therefore operate with a more direct relational structure. Bystander models,

by contrast, require a broader map that includes bystander-victim, bystander-negotiator, and victim-negotiator relations. Because these mechanisms differ substantively, the victim and bystander specifications cannot be treated as interchangeable. Role-specific models are therefore necessary both statistically and theoretically.

The five hypothesis families follow naturally from this structure. H1 models **judgement** as a function of empathy with the common acceptance adjustment. H2 focuses on role-specific group alignment with the same acceptance adjustment. H3 combines empathy and group structure with theoretically motivated interactions plus the same acceptance adjustment. H4 models judgement as a function of **accept_target**, **accept_other**, and their interaction as the central block. H5 integrates all previous components into a single specification. This progression allows the analysis to move from simpler explanations toward a more comprehensive account of moral judgement.

A key principle of the workflow is that one row remains one real target-judgement observation. The pipeline does not duplicate rows into separate pseudo-observations for negotiators, because doing so would artificially inflate the sample size and distort inference. Instead, the relational context involving target, other, victim, and bystander is retained within each existing row. This preserves the integrity of the long-format design while maintaining the proper unit of analysis.

Taken together, the current production strategy has several strengths. It respects the bounded structure of the outcome, preserves the long-format observational design, adjusts inference for repeated observations, controls for session-level heterogeneity, separates victim and bystander mechanisms, and maps directly onto the theoretical architecture of H1 through H5. At the same time, its limitations must also be recognized. The estimator is not a full mixed-effects Tobit with random participant and session intercepts. In addition, sparse role-specific cells may still produce rank-deficient contrasts in interaction-heavy models. For that reason, interpretation should rely on the full combination of coefficient tables and model-implied figures rather than on isolated p-values.

Overall, the current production pipeline is statistically and conceptually aligned with the experiment. It treats bounded continuous moral judgement with a two-sided Tobit model, handles repeated observations through participant-cluster robust inference, adjusts session heterogeneity through fixed effects, and preserves role-specific relational theory within model specification. This makes the present workflow a defensible production framework, while also leaving a clear path for future multilevel Tobit extensions.

2 Semantic naming bridge and row-level mapping

Source/legacy naming bridge: `decision_target` -> active operational name `accept_target`; `decision_other` -> active operational name `accept_other`.

Row-level semantics: `target` and `other` are dynamic roles per observation; all active analytical terms in this report are expressed directly in that pair.

Table 1. Row-level decision mapping from dynamic target/other to legacy structural-slot mappings

rule	expected_mappings	rows_in_scope	rows_following	status
target == 1	Judged actor = target code 1, counterpart = other code 2; judged decision is <code>accept_target</code> , counterpart decision is <code>accept_other</code> .	2430	2430	PASS
target == 2	Judged actor = target code 2, counterpart = other code 1; judged decision is <code>accept_target</code> , counterpart decision is <code>accept_other</code> .	2430	2430	PASS

3 Dataset and sample description

The report uses the consolidated long experimental dataset as the single analytical source. Each participant contributes 20 judgement rows in principle: ten scenarios multiplied by two target-negotiator evaluations. Each imported row remains one real judgement observation on the target negotiator, enriched with relational context for target, other, victim, and bystander without duplicating rows. Double counting is prevented because target and other remain contextual attributes inside

each existing row rather than by expanding the file into duplicated negotiator-specific observations. Victim and bystander analyses are estimated separately so that relational coding follows the role-specific logic of the experiment.

The authoritative interpretation is that each player observes ten scenarios and evaluates two negotiators, so the longitudinal file should contain 20 judgement rows per participant. The clustering diagnostic below is consistent with that design.

Table 2. Participant summary

metric	value
participants	243.000
sessions	16.000
mean_age	20.086
women_share	0.426
engineering_share	0.568

Table 3. Judgement summary

sample	rows	participants	mean_judgement	sd_judgement
All	4860	243	1.623	6.674
Victim	2430	243	1.504	6.842
Bystander	2430	243	1.741	6.500

4 Datacard and symbol dictionary

Table 4. Datacard symbol dictionary

symbol	definition
judgement	Observed moral judgement on the bounded scale from -9 to 9.
y*	Latent judgement tendency underlying the censored Tobit observation.
iri_fs / iri_ec / iri_pt / iri_pd	IRI empathy dimensions: fantasy, empathic concern, perspective taking, and personal distress.
target (row-dynamic)	Judged negotiator in that row; this role is dynamic and determined by the row-level target code.
other (row-dynamic counterpart)	Counterpart negotiator in that same row context (the non-target actor).

symbol	definition
target / other (analytical pair)	Analytical target/other pair used for relational modeling without fixed structural negotiator identities.
accept_target	Indicator for whether the row-dynamic target negotiator accepted the harmful deal; active operational name with a legacy bridge from decision_target.
accept_other	Indicator for whether the row-dynamic other negotiator accepted the harmful deal; active operational name with a legacy bridge from decision_other.
decision_target / decision_other (legacy source)	Original source-file column names retained for compatibility and audit; the active analytical layer uses accept_target and accept_other .
victim_target_group / victim_other_group	Victim-specific relations to target and other, with ingroup defined by faculty coincidence including control-control matches.
bystander_victim_group / bystander_target_group / bystander_other_group	Bystander-side relational factors for the victim and both negotiators, again using faculty coincidence as ingroup.
group_target / group_other (legacy audit)	Legacy source grouping fields retained for provenance checks; not used directly in active H2/H3/H5 formulas.
target_other_same_faculty	Context term indicating whether target and other share faculty membership.
factor(session)	Session fixed effects included directly in every fitted formula.
cluster = id	Participant-level clustering used for robust standard errors and repeated-measures adjustment.
Log(scale)	Estimated Tobit log-scale parameter summarizing latent residual dispersion.

Table 5. Observation audit

checkpoint	value
base_excel_rows	4860
processed_import_rows	4860

checkpoint	value
processed_judgment_rows	4860
unique_source_row_numbers	4860
duplicated_source_row_numbers	0

5 Predictor glossary

Table 6. Predictor glossary (reader version)

Code	Interpretation
FS	Fantasy empathy dimension.
EC	Empathic concern empathy dimension.
PT	Perspective-taking empathy dimension.
PD	Personal-distress empathy dimension.
V-Tgt In	Victim and target are from the same faculty.
V-Tgt Out	Victim and target are from different faculties.
V-Oth In	Victim and other are from the same faculty.
V-Oth Out	Victim and other are from different faculties.
B-V Out	Bystander and victim are from different faculties.
B-Tgt In	Bystander and target are from the same faculty.
B-Tgt Out	Bystander and target are from different faculties.
B-Oth In	Bystander and other are from the same faculty.
B-Oth Out	Bystander and other are from different faculties.
SameFac	Target and other share faculty membership.
FS x V-Tgt Out	Fantasy slope difference when victim-target is outgroup rather than ingroup.
EC x V-Oth Out	Empathic-concern slope difference when victim-other is outgroup rather than ingroup.

Code	Interpretation
PT x B-V Out	Perspective-taking slope difference when the bystander-victim relation is outgroup rather than ingroup.
PD x B-Tgt Out	Personal-distress slope difference when the bystander-target relation is outgroup rather than ingroup.
Target Acc	Row-dynamic target negotiator accepted the harmful deal (legacy source name: decision_target).
Other Acc	Row-dynamic counterpart negotiator accepted the harmful deal (legacy source name: decision_other).
Target x Other	Joint decision effect when both negotiator decisions are considered together.
Eng part.	Participant belongs to Engineering, relative to Humanities.
Woman	Participant is a woman.
Age	Participant age.
SES	Participant socioeconomic status.

Note. Group contrasts are interpreted against the ingroup baseline unless explicitly stated otherwise.

The report keeps compact predictor references in figure captions and narratives, but the glossary above remains the authoritative mapping back to the current pipeline variables.

6 Interaction interpretation rules

1. When an interaction is statistically relevant, the main effects should be read as the baseline component of the relationship rather than the whole substantive story.
2. Continuous-by-factor interactions indicate that the empathy slope changes across relational conditions.
3. Factor-by-factor interactions indicate that the joint context differs from what would be expected by adding the two main contrasts independently.
4. The target-by-other decision interaction indicates that the moral meaning of one negotiator's choice depends on what the counterpart did.
5. Session effects are adjustment terms only and are not interpreted as substantive experimental mechanisms.

7 H1-H5 hypotheses with role-specific equation summaries

Table 1: H1-H5 role-specific formulas and theoretical focus.

H	Role	Formula	Focus
H1	Victim	iri_fs + iri_ec + iri_pt + iri_pd + accept_target * accept_other + age + ses + sex_female + faculty_player_factor + factor(session)	Empathy dimensions with the common accept_target x accept_other adjustment and sociodemographics.
H1	Bystander	iri_fs + iri_ec + iri_pt + iri_pd + accept_target * accept_other + age + ses + sex_female + faculty_player_factor + factor(session)	Empathy dimensions with the common accept_target x accept_other adjustment and sociodemographics.
H2	Victim	victim_target_group + victim_other_group + victim_target_group : victim_other_group + target_other_same_faculty + accept_target * accept_other + age + ses + sex_female + faculty_player_factor + factor(session)	Victim-side ingroup/outgroup structure with the allowed target x other relational interaction and the common accept_target x accept_other adjustment.
H2	Bystander	bystander_victim_group + bystander_target_group + bystander_other_group + victim_target_group + victim_other_group + bystander_target_group : bystander_other_group + victim_target_group : victim_other_group + target_other_same_faculty + accept_target * accept_other + age + ses + sex_female + faculty_player_factor + factor(session)	Bystander-side relational structure with explicit bystander-victim, bystander-target, bystander-other, target/other context terms, and the common accept_target x accept_other adjustment.
H3	Victim	iri_fs + iri_ec + iri_pt + iri_pd + victim_target_group + victim_other_group + victim_target_group : victim_other_group + target_other_same_faculty + iri_fs : victim_target_group + iri_fs : victim_other_group + iri_ec : victim_target_group + iri_ec : victim_other_group + iri_pt : victim_target_group + iri_pt : victim_other_group + iri_pd : victim_target_group + iri_pd : victim_other_group + accept_target * accept_other + age + ses + sex_female + faculty_player_factor + factor(session)	Empathy plus victim-side relational structure, including empathy x victim-target and empathy x victim-other interactions, with the common accept_target x accept_other adjustment.

H	Role	Formula	Focus
H3	Bystander	$ \begin{aligned} & \text{iri_fs} + \text{iri_ec} + \text{iri_pt} + \text{iri_pd} + \\ & \text{bystander_victim_group} + \text{bystander_target_group} + \\ & \text{bystander_other_group} + \text{victim_target_group} + \\ & \text{victim_other_group} + \text{bystander_target_group} : \\ & \text{bystander_other_group} + \text{victim_target_group} : \\ & \text{victim_other_group} + \text{target_other_same_faculty} + \\ & \text{iri_fs} : \text{bystander_victim_group} + \text{iri_fs} : \\ & \text{bystander_target_group} + \text{iri_fs} : \\ & \text{bystander_other_group} + \text{iri_ec} : \\ & \text{bystander_victim_group} + \text{iri_ec} : \\ & \text{bystander_target_group} + \text{iri_ec} : \\ & \text{bystander_other_group} + \text{iri_pt} : \\ & \text{bystander_victim_group} + \text{iri_pt} : \\ & \text{bystander_target_group} + \text{iri_pt} : \\ & \text{bystander_other_group} + \text{iri_pd} : \\ & \text{bystander_victim_group} + \text{iri_pd} : \\ & \text{bystander_target_group} + \text{iri_pd} : \\ & \text{bystander_other_group} + \text{accept_target} * \text{accept_other} \\ & + \text{age} + \text{ses} + \text{sex_female} + \text{faculty_player_factor} + \\ & \text{factor}(\text{session}) \end{aligned} $	Empathy plus bystander-side relational structure, including empathy x bystander-victim and empathy x bystander-target/other interactions, with the common accept_target x accept_other adjustment.
H4	Victim	$ \begin{aligned} & \text{accept_target} * \text{accept_other} + \text{age} + \text{ses} + \text{sex_female} \\ & + \text{faculty_player_factor} + \text{factor}(\text{session}) \end{aligned} $	Target and other negotiator acceptance terms with their interaction, plus sociodemographics.
H4	Bystander	$ \begin{aligned} & \text{accept_target} * \text{accept_other} + \text{age} + \text{ses} + \text{sex_female} \\ & + \text{faculty_player_factor} + \text{factor}(\text{session}) \end{aligned} $	Target and other negotiator acceptance terms with their interaction, plus sociodemographics.
H5	Victim	$ \begin{aligned} & \text{iri_fs} + \text{iri_ec} + \text{iri_pt} + \text{iri_pd} + \text{victim_target_group} + \\ & \text{victim_other_group} + \text{victim_target_group} : \\ & \text{victim_other_group} + \text{target_other_same_faculty} + \\ & \text{iri_fs} : \text{victim_target_group} + \text{iri_fs} : \\ & \text{victim_other_group} + \text{iri_ec} : \text{victim_target_group} + \\ & \text{iri_ec} : \text{victim_other_group} + \text{iri_pt} : \\ & \text{victim_target_group} + \text{iri_pt} : \text{victim_other_group} + \\ & \text{iri_pd} : \text{victim_target_group} + \text{iri_pd} : \\ & \text{victim_other_group} + \text{accept_target} * \text{accept_other} + \\ & \text{age} + \text{ses} + \text{sex_female} + \text{faculty_player_factor} + \\ & \text{factor}(\text{session}) \end{aligned} $	Integrated model with empathy, victim-side relations, empathy x group interactions, acceptance terms, and the victim-side target/other interaction.
H5	Bystander	$ \begin{aligned} & \text{iri_fs} + \text{iri_ec} + \text{iri_pt} + \text{iri_pd} + \\ & \text{bystander_victim_group} + \text{bystander_target_group} + \\ & \text{bystander_other_group} + \text{victim_target_group} + \\ & \text{victim_other_group} + \text{bystander_target_group} : \\ & \text{bystander_other_group} + \text{victim_target_group} : \\ & \text{victim_other_group} + \text{target_other_same_faculty} + \\ & \text{iri_fs} : \text{bystander_victim_group} + \text{iri_fs} : \\ & \text{bystander_target_group} + \text{iri_fs} : \\ & \text{bystander_other_group} + \text{iri_ec} : \\ & \text{bystander_victim_group} + \text{iri_ec} : \\ & \text{bystander_target_group} + \text{iri_ec} : \\ & \text{bystander_other_group} + \text{iri_pt} : \\ & \text{bystander_victim_group} + \text{iri_pt} : \\ & \text{bystander_target_group} + \text{iri_pt} : \\ & \text{bystander_other_group} + \text{iri_pd} : \\ & \text{bystander_victim_group} + \text{iri_pd} : \\ & \text{bystander_target_group} + \text{iri_pd} : \\ & \text{bystander_other_group} + \text{accept_target} * \text{accept_other} \\ & + \text{age} + \text{ses} + \text{sex_female} + \text{faculty_player_factor} + \\ & \text{factor}(\text{session}) \end{aligned} $	Integrated model with empathy, bystander-side relations, empathy x group interactions, acceptance terms, and role-specific target/other relational interactions.

Any earlier repository note that treated negotiator code 0 as anything other than the explicit control category, or that narrowed H3 to additive effects only, should

now be treated as outdated. The active formulas below are the authoritative specification.

7.1 H1

Victim: iri_fs + iri_ec + iri_pt + iri_pd + accept_target *
accept_other + age + ses + sex_female + faculty_player_factor
+ factor(session)

accept_target * accept_other + age + ses + sex_female + faculty_player_factor
+ factor(session)`

8 Mathematical foundations

The primary estimator is a two-sided Tobit fitted with `survival::survreg`.

$$y_i = \max(-9, \min(9, y_i^*))$$

$$y_i^* = \beta_0 + X_i\beta + \delta_{session(i)} + \varepsilon_i$$

where `factor(session)` supplies session fixed effects and cluster-robust standard errors are computed at the participant level through `cluster = id` with `robust = TRUE`. This report therefore treats session as an implemented fixed-effect adjustment, not as a random intercept.

In this production branch, `factor(session)` is reported instead of `(1|session)` because the fitted estimator is a two-sided Tobit with session fixed effects and

participant-cluster robust standard errors. The report does not claim a random session intercept that was not actually estimated.

9 Dependence and effective sample size diagnostic

The following clustering diagnostic is descriptive. It summarizes within-participant dependence in the observed data and should not be read as evidence that the fitted estimator included participant random intercepts.

Table 7. Descriptive clustering diagnostic

metric	value
participants	243.000
observations	4860.000
average_observations_per_id	20.000
icc_descriptive	0.134
design_effect	3.537
effective_sample_size	1373.909

Because the target of inference is repeated judgement within participant, the effective-sample-size table is a descriptive clustering diagnostic only; it does not replace the model-based dependence adjustment through `cluster = id` and `factor(session)`.

10 Descriptive statistics and figures

Table 8. Decision summary by role

role_label	decision_pattern	n	mean_judgement
bystander	both_accept	604	-2.785
victim	both_accept	610	-3.167
bystander	both_reject	690	7.086
victim	both_reject	662	7.062
bystander	target_accept_other_reject	568	-3.155
victim	target_accept_other_reject	579	-3.803
bystander	target_reject_other_accept	568	4.958
victim	target_reject_other_accept	579	5.378

Table 9. Role-specific ingroup/outgroup summary

variable	level	n
victim_target_group	ingroup	1630
victim_target_group	outgroup	3230
victim_other_group	ingroup	1630
victim_other_group	outgroup	3230
bystander_victim_group	ingroup	1212
bystander_victim_group	outgroup	1218
bystander_target_group	ingroup	805
bystander_target_group	outgroup	1625
bystander_other_group	ingroup	805
bystander_other_group	outgroup	1625
target_other_same_faculty	different	3276
target_other_same_faculty	same	1584

Table 10. Participant-level empathy and mean judgement correlation matrix

term	iri_fs	iri_ec	iri_pt	iri_pd	judgement
iri_fs	1.000	0.409	0.154	0.282	0.051
iri_ec	0.409	1.000	0.482	0.219	-0.017
iri_pt	0.154	0.482	1.000	-0.177	0.111
iri_pd	0.282	0.219	-0.177	1.000	-0.046
judgement	0.051	-0.017	0.111	-0.046	1.000

The group summary and the formulas above use role-specific ingroup/outgroup coding. Ingroup is defined by faculty coincidence, including `control` with `control`, while outgroup means non-matching faculties.

This figure summarizes the central empathy profile of the sample before conditioning on hypothesis-specific models.

These scatterplots show the participant-level descriptive relationship between empathy dimensions and average judgement.

This figure shows the raw shape of the bounded judgement outcome in the victim and bystander subsets.

This figure shows whether the raw bounded judgement distribution differs depending on whether the target code is 1 or 2 within victim and bystander settings.

This figure isolates whether the target’s own acceptance or rejection is associated with different raw judgement profiles within each role.

This figure shows whether judgement of the target varies with the acceptance or rejection of the other negotiator.

Figure 1: Mean IRI subscale profile across participants.

Figure 2: Participant-level bivariate scatters of IRI subscales against mean judgement.

Figure 3: Observed judgement distributions split by role.

Figure 4: Observed judgement distributions by role and target negotiator.

Figure 5: Observed judgement distributions by role and target decision.

Figure 6: Observed judgement distributions by role and counterpart decision.

Figure 7: Observed judgement distributions by role and joint decision pattern.

This figure shows how the target-focused judgement distribution changes across the four joint negotiation outcomes in victim and bystander settings.

Figure 8: Observed decision-pattern counts by role.

This figure summarizes how often each joint decision pattern appears in victim and bystander subsets.

This figure shows how the raw judgement distribution varies across the full relational space defined by the faculty pairing of target and other.

This figure shows how the raw judgement distribution varies across the full relational space defined by the faculty pairing of target and other.

This optional figure highlights how raw victim-role judgement varies across victim-centered ingroup/outgroup combinations.

This optional figure emphasizes bystander-side relational combinations directly tied to target/other group alignment.

This optional figure shows how bystander judgement co-varies with victim-centered relational combinations in the same observed rows.

11 Estimator fit summary

Bystander models use 2,420 observations from 243 participants. Victim models use 2,420 observations from 243 participants.

All production models use the estimator configuration shown below.

In the H1 Bystander model, no focal hypothesis term reached $p < 0.10$. The report therefore retains the coefficient table for auditability but does not attach a significance-driven substantive interpretation beyond the descriptive prediction plots.

H2 reminder: active relational predictors are expressed with row-dynamic **target/other** semantics; **group_target** and **group_other** remain legacy source-audit fields and are not active H2 predictors.

The H5 Bystander model shows focal evidence for 7 hypothesis terms. Target accepted is associated with lower predicted judgement (estimate = -15.38, $p = <0.001$). ***Other negotiator accepted is associated with lower predicted judgement (estimate = -4.27, $p = <0.001$).*** Target accepted x Other accepted is associated with higher predicted judgement (estimate = 4.88, $p = <0.001^{***}$). Session dummies remain in the fitted estimator for adjustment but are intentionally omitted from the substantive narrative.

15 Compliance checklist

Table 26. Pipeline compliance checklist

criterion	status	evidence
a) uses judgement	YES	All formulas model judgement directly.
b) repeated structure by id	YES	All fitted Tobit models use participant-cluster robust standard errors through cluster = id.
c) session grouping	YES	The active Tobit branch uses factor(session) in every formula and documents that choice explicitly instead of claiming a random session intercept.
d) no double count introduced by the pipeline	YES	Imported rows = 4860; final analytical rows = 4860; duplicated source row numbers introduced by the pipeline = 0.
e) victim and bystander treated differently	YES	Role-specific formulas are estimated separately and H2/H3/H5 use different relational blocks for victim and bystander.
f) accept_target and accept_other included in H1-H5	YES	All H1-H5 formulas include accept_target, accept_other, and their interaction as part of the active specification.
g) sociodemographics included in every hypothesis model	YES	Every H1-H5 formula retains age, ses, sex_female, and faculty_player_factor.

16 Corrections relative to outdated notes

The current production branch supersedes earlier notes that used `control_hidden` wording for negotiator code 0, narrowed H3 to additive-only empathy terms, or implied that the main estimator used `(1|session)`. The

repository now documents the implemented estimator and the authoritative role-specific design directly.

17 Limitations

The production branch does not fit a full multilevel Tobit with explicit random participant and session intercepts inside the same estimator. Sparse relational cells can produce rank-deficient design matrices, so some interaction contrasts are dropped automatically and reported as such. The dynamic figures visualize model-implied predictions from the saved primary Tobit fits and should be interpreted jointly with the coefficient tables rather than as standalone causal effects.

18 Discussion

The empathy results speak to a mechanism in which moral judgement is not only a response to outcomes but also to dispositional social sensitivity. When empathy slopes vary across ingroup and outgroup relations, the findings support the original theoretical expectation that empathic orientation is filtered through perceived social closeness rather than operating as a uniform moral amplifier.

The ingroup/outgroup results matter because the experiment embeds judgement in a relational structure with two negotiators and role-dependent social ties. Victim and bystander models are therefore not interchangeable. In the victim role, the central question is how the judged negotiator and the counterpart relate to the harmed person. In the bystander role, the participant is socially external to the harm event, so judgement can depend on a broader map that includes bystander-victim, bystander-negotiator, and victim-negotiator alignments.

The decision terms sharpen the moral interpretation of the target-focused outcome. `accept_target` captures what the judged negotiator did, `accept_other` captures the counterpart's choice, and their interaction tests whether the meaning of one decision changes when the other negotiator accepts or rejects. This is substantively important because moral evaluations of the target can respond both to individual action and to the joint negotiation outcome.

Practically, the results speak to negotiation ethics and third-party evaluation. If moral judgement shifts with empathy, faculty closeness, and joint decision patterns, then perceived fairness in harmful negotiations is shaped by both dispositional and relational context. That has implications for how observers assign blame, excuse strategic behavior, or infer responsibility from coordinated action.

Methodologically, the active estimator is a two-sided Tobit with participant-cluster robust standard errors and session fixed effects. This is an honest production choice for a bounded repeated-measures outcome because it preserves the

Tobit structure for `judgement`, adjusts within-participant dependence through clustering by `id`, and controls for session-level shifts through `factor(session)`. At the same time, it is not equivalent to a fully mixed Tobit with random participant and session intercepts, so dependence is handled through robust inference plus fixed-effects adjustment rather than a full hierarchical likelihood.

The main limitations follow directly from that estimator choice and from the sparsity of some relational cells. The production branch does not estimate a full mixed Tobit, some interaction contrasts may be dropped in rank-deficient subsets, and any substantive reading should remain tied to the coefficient tables and model-implied figures rather than to isolated p-values. Future work should compare these production estimates against stable multilevel censored models, test alternative role-specific interaction sets, and examine whether the same theoretical patterns replicate under additional institutional or cultural contexts.

19 Final audit note

The project now faithfully reflects the authoritative design in its production branch: `judgement` is the outcome, the long file remains the single source, one row remains one real observation, role-specific group definitions are used, `accept_target` and `accept_other` are modeled in H1-H5, and repeated measurements are handled through participant-cluster robust inference with `factor(session)`.

No rank-deficiency warning remained in the saved fit summary for this run.

Estimator limitation: the production estimator is still a two-sided Tobit with `factor(session)` and participant-cluster robust standard errors by `id`, not a full mixed-effects Tobit with random participant and session intercepts.

21 Conclusion

The conclusions presented here should be interpreted as associational rather than causal. In this report, moral judgement was estimated with a two-sided Tobit model that handles censoring, repeated participant observations, and session adjustment through `factor(session)` with participant-cluster robust inference.

This conclusion section cross-references the full report structure. It should be read together with the H1-H5 equation summaries, the hypothesis significance summary by role, the full coefficient tables and interpretation summary, and the significance-driven figures.

21.1 Hypothesis-by-hypothesis synthesis

21.1.1 H1

H1 evaluates empathy as a direct predictor of moral judgement while retaining common controls. For cross-reference, see the H1 equation summary and the H1 role-specific coefficient tables and figures. In the victim role, the role-specific support summary highlighted: Empathy: Perspective taking*. In the bystander role, no focal term reached the $p < 0.10$ threshold in the role-specific summary table. Taken together, H1 suggests that the role position conditions how clearly empathy appears in the fitted judgement pattern.

21.1.2 H2

H2 reminder: active relational predictors are expressed with row-dynamic `target/other` semantics; `group_target` and `group_other` remain legacy source-

audit fields and are not active H2 predictors.

H2 focuses on role-specific ingroup/outgroup structure. For cross-reference, see the H2 equation summary and the H2 role-specific coefficient tables and figures. In the victim role, no focal term reached the $p < 0.10$ threshold in the role-specific summary table. In the bystander role, the role-specific support summary highlighted: Victim-target outgroup vs ingroup; *Victim-target outgroup vs ingroup x Victim-other outgroup vs ingroup*. This comparison indicates that relational alignment cues are not equally informative across roles, and they can become more visible when participants evaluate as observers rather than as directly harmed actors.

21.1.3 H3

H3 combines empathy, group structure, and interaction terms. For cross-reference, see the H3 equation summary, the H3 coefficient tables, and the H3 interaction figures. In the victim role, the role-specific support summary highlighted: Empathy: Fantasy; *Victim-target outgroup vs ingroup*; Empathy: Fantasy x Victim-other outgroup vs ingroup+. In the bystander role, the role-specific support summary highlighted: Victim-target outgroup vs ingroup; *Victim-other outgroup vs ingroup+*; *Victim-target outgroup vs ingroup x Victim-other outgroup vs ingroup*; Empathy: Fantasy x Bystander-victim outgroup vs ingroup*. The H3 evidence should therefore be interpreted as a test of contextual moderation: empathy does not necessarily operate as a uniform slope when social distance changes.

21.1.4 H4

H4 reminder: legacy source `decision_target` corresponds to active `accept_target`, and `decision_other` corresponds to active `accept_other`; both refer to row-dynamic `target/other` roles.

H4 tests decision terms directly through `accept_target`, `accept_other`, and their interaction. For cross-reference, see the H4 equation summary and the H4 role-specific coefficient tables and significance figures. In the victim role, the role-specific support summary highlighted: Target accepted; ***Other negotiator accepted***; Target accepted x Other accepted. ***In the bystander role, the role-specific support summary highlighted: Target accepted***; Other negotiator accepted; ***Target accepted x Other accepted***. Across both roles, H4 is typically where the decisional mechanism is most clearly visible, because the target judgement is explicitly conditioned by joint negotiation outcomes.

21.1.5 H5

H5 reminder: the integrated specification keeps `target/other` semantics for relational and acceptance terms; `group_target/group_other` remain legacy audit fields, and legacy source `decision_target/decision_other` maps to active `accept_target/accept_other`.

H5 is the integrated specification combining empathy, relational terms, decisions, and interactions. For cross-reference, see the H5 equation summary, H5 coefficient tables, and H5 significance figures. In the victim role, the role-specific support summary highlighted: Empathy: Fantasy; *Victim-target outgroup vs ingroup*; Target accepted; ***Other negotiator accepted***; Empathy: Fantasy x Victim-other outgroup vs ingroup+; Target accepted x Other accepted. ***In the bystander role, the role-specific support summary highlighted: Victim-target outgroup vs ingroup; Victim-other outgroup vs ingroup+; Target accepted; Other negotiator accepted; Victim-target outgroup vs ingroup x Victim-other outgroup vs ingroup; Empathy: Fantasy x Bystander-victim outgroup vs ingroup; Target accepted x Other accepted****. H5 should be read as a synthesis rather than a replacement of previous hypotheses: it shows how dispositional, relational, and decisional components coexist in one model.

21.2 Overall interpretation

Taken as a whole, the five hypotheses indicate that moral judgement in this experiment is multi-mechanistic rather than one-dimensional. Empathy-related terms can matter, relational alignment can matter, and decision terms can matter strongly, but their visibility changes by role and model context.

In practical terms, the report supports a role-contingent interpretation: victim-side judgement retains stronger dispositional content in some specifications, while bystander-side judgement often shows greater dependence on relational context, and both roles remain sensitive to the joint decisions made by negotiators.
